### Date/Event/Venue:

13-15 October, 2010  
11th International Symposium "Interdisciplinary Regional Research"  
Szeged, Hungary

### Introduction

Collagen-based biomaterials are increasingly appreciated by specialists in dentistry. Although they enjoy remarkable attention, they are still under research and/or clinical trial. The purpose of the drug delivery systems (DDS) is the controlled release of drugs on the affected tissue. Several interdisciplinary fields as polymer science, pharmacy, chemistry, molecular biology and dentistry are involved in the development of such complex biomaterials.

Collagen is a suitable support for drug delivery, offering the advantage of a natural biomaterial with haemostatic and wound healing properties. Lidocaine belongs to the local anesthetics class and it is used to relieve the pain by stopping nerves from sending pain signals.

### Objectives

The aim of this study is developing wound dressings in form of collagen spongius matrices with lidocaine as drug for their using in dentistry.

### Material and Methods

Type I fibrillar collagen gel having a concentration of 1.71% (w/w) was extracted from calf hide by the currently used technology in Collagen Department. Lidocaine was purchased from Sigma-Aldrich and glutaraldehyde (GA) was obtained from Merck (Germany). Sodium hydroxide and phosphate buffer solution (PBS), pH, 7.4 were of analytical grade.

Collagen hydrogels with concentrations of 1.0, 1.2 and 1.4% in collagen and 0.1% lidocaine were obtained in aqueous solutions, at 7.4 pH. These hydrogels were freeze-dried using the Christ Model Delta 2-24 LSC freeze-dryer, Germany and proper collagen matrices (spongius forms) were obtained.

FT-IR spectrum measurements were recorded by FT-IR spectrophotometer of Perkin Elmer type Spectrum 100.

The water absorption was calculated using the method previous described [4].

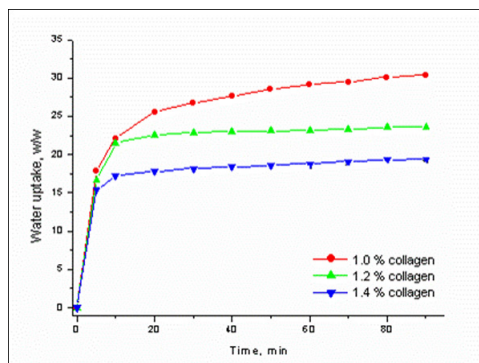

In vitro release of lidocaine was determined in triplicate at 37° C using a modified USP paddle method ("sandwich" device). The amount of lidocaine released was spectrophotometrically determined at 263 nm.

Clinical trials were carried out on 40 patients with the cronical apical parodontitis and with rest roots for who have been performed extractions.

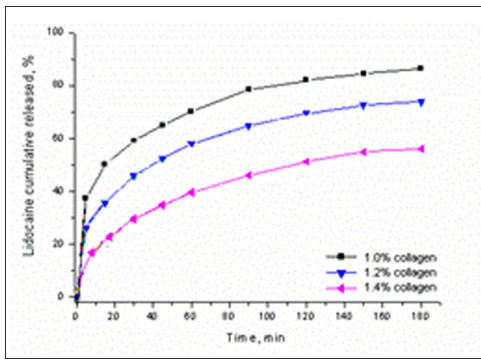

For 10 of this patients the alveols were lets to heal naturrally-the witness lot and the rest of 30 patients were divided in 3 groups corresponding to the collagen concentrations(1.0, 1.2 and 1.4% in collagen/the group A, B, C).

FT-IR spectra for collagen matrix with 1% collagen and 0.1% lidocaine

Water uptake for collagen matrices

In vitro lidocaine release from collagen matrices

## Results

The infrared spectra of collagen exhibit several features characteristic for the molecular organization of its molecules: amino acids linked together by peptide bonds give rise to infrared active vibration modes amide A and B (about 3330 and 3080  $\text{cm}^{-1}$ , respectively) and amide I, II, and III (about 1650, 1550 and 1250  $\text{cm}^{-1}$ , respectively).

Figure 1 shows the FT-IR spectrum for matrix with 1% collagen and 0.1% lidocaine.

In the spectrum of the collagen matrix, shown in Figure 1, the five characteristic absorption bands can be observed at 3314, 2958, 1634, 1548 and 1238  $\text{cm}^{-1}$ . The characteristic collagen bands indicate that triple helix structure was preserved in all the samples.

Water uptake studies showed that swelling was influenced by the collagen concentrations (Fig. 2).

As the Figure 2 shows, the higher collagen concentration, slower is swelling ability.

The drug release was performed for collagen matrices in order to evaluate the amount of lidocaine released. The release profiles of lidocaine from the collagen matrices are presented in Figure 3.

Figure 3 shows that higher collagen concentrations produce the decreasing of the amount of lidocaine released.

The results for the lidocaine release are in close agreement with the spectral characteristics and water uptake data.

In comparison to the witness group at all the other three lots, the clinical parameters- coagulation, bleeding, healing time/immediate post-extractional, and healing time at 1, 3, 7 days post-extractional were improved.

The best results have been obtained in the group for which the matrices 1.4% in collagen concentration was applied (the lot C).

In this group, the healing of the alveole is highly set toward to the witness lot and better in comparison to the other two groups of patients. (Fig. 5-11)

Healing with the collagen matrix

Healing with 1.4 collagen matrices

The witness alveole, 1.10, 1.2 collagen matrix

Healing with 1.0 collagen matrices

Healing with 1.4 collagen matrices

Healing with 1.0 collagen matrices

Healing with 1.2 collagen matrices

Healing with 1.4 collagen matrices

## Conclusions

Collagen matrices containing lidocaine were obtained from proper gels at pH 7.4 by the freeze-drying process. The collagen matrices release lidocaine more slowly from samples with higher concentration in collagen.

Clinical trial reveals in vivo the quality of healing at 1,3,7 days post-extractional , decrease the pain of patients immediate after extraction and the shorter bleeding,coagulation and healing time in the three groups which was applied the collagen matrices comparison to the witness group.

## INTRODUCTION

Collagen-based biomaterials are increasingly appreciated by specialists in dentistry. Although they enjoy remarkable attention, they are still under research and/or clinical trial. The purpose of the drug delivery systems (DDS) is the controlled release of drugs on the affected tissue. Several interdisciplinary fields as polymer science, pharmacy, chemistry, molecular biology and dentistry are involved in the development of such complex biomaterials. Collagen is a suitable support for drug delivery, offering the advantage of a natural biomaterial with hemostatic and wound-healing properties [1, 2]. Lidocaine belongs to the local anesthetics class and it is used to relieve the pain by stopping nerves from sending pain signals [3].

## OBJECTIVE

The aim of this study is developing wound dressings in form of collagen spongy matrices with lidocaine as drug for their using in dentistry.

## MATERIAL AND METHODS

Type I fibrillar collagen gel having a concentration of 1.71% (w/w) was extracted from calf hide by the currently used technology in Collagen Department [4]. Lidocaine was purchased from Sigma-Aldrich and glycylglycyl-L-glycine (GA) was obtained from Merck (Germany). Sodium hydroxide and phosphate buffer solution (PBS), pH 7.4 were of analytical grade.

Collagen hydrogels with concentrations of 1.0, 1.2 and 1.4% in collagen and 0.1% lidocaine were obtained in aqueous solutions, at 7.4 pH. These hydrogels were freeze-dried using the Christ Model Delta 2-24 LSC freeze-dryer, Germany and proper collagen matrices (spongy forms) were obtained.

FT-IR spectrum measurements were recorded by FT-IR spectrophotometer of Perkin Elmer type Spectrum 100.

The water absorption was calculated using the method previously described [4]. In vitro release of lidocaine was determined in triplicate at 37.0±0.5°C using a modified USP paddle method ("sandwich" device). The amount of lidocaine released was spectrophotometrically determined at 263 nm. Clinical trials were carried out on 40 patients with the chronic apical periodontitis and with rest roots for who have been performed extractions.

For 10 of the patients the alveols were left to heal naturally-the witness lot and the rest of 30 patients were divided in 3 groups corresponding to the collagen concentrations (1.0, 1.2 and 1.4% in collagen) the group A, B, C.

## RESULTS

The infrared spectra of collagen exhibit several features characteristic for the molecular organization of its molecules: amino acids linked together by peptide bonds give rise to infrared active vibration modes amide A and B (about 3330 and 3080 cm<sup>-1</sup>, respectively) and amide I, II, and III (about 1650, 1550 and 1250 cm<sup>-1</sup>, respectively) [5].

Figure 1 shows the FT-IR spectrum for matrix with 1% collagen and 0.1% lidocaine.

In the spectrum of the collagen matrix, shown in Figure 1, the five characteristic absorption bands can be observed at 3314, 2968, 1634, 1548 and 1238 cm<sup>-1</sup>. The characteristic collagen bands indicate that triple helix structure was preserved in all the samples.

Water uptake studies showed that swelling was influenced by the collagen concentrations (Figures 2).

As the Figure 2 shows, the higher collagen concentration, slower is swelling ability.

The drug release was performed for collagen matrices in order to evaluate the amount of lidocaine released. The release profiles of lidocaine from the collagen matrices are presented in Figure 3.

The Figure 3 shows that higher collagen concentrations produce the decreasing of the amount of lidocaine released.

The results for the lidocaine release are in close agreement with the spectral characteristics and water uptake data.

In comparison to the witness group at all the other three lots, the clinical parameters- coagulation, bleeding, healing time (immediate post-extractional, and healing time at 1, 3, 7 days post-extractional) were improved.

The best results have been obtained in the group for which the matrices 1.4% in collagen concentration was applied (the lot D).

In this group, the healing of the alveole is highly set toward to the witness lot and better in comparison to the other two groups of patients (Fig.5-11).

## CONCLUSIONS

Collagen matrices containing lidocaine were obtained from proper gels at pH 7.4 by the freeze-drying process. The collagen matrices release lidocaine more slowly from samples with higher concentration in collagen.

Clinical trial reveals in vivo the quality of healing at 1,3,7 days post-extractional, decrease the pain of patients immediate after extraction and the shorter bleeding, coagulation and healing time in the three groups which was applied the collagen matrices comparison to the witness group.
