September 24-27, 2008
FDI Annual World Dental Congress
Stockholm, Sweden

Introduction

Differences between clasps removable partial dentures and composites dentures are functional and aesthetical. The last ones need the using of some special maintaining, support and stabilization systems associated with high precision millings. The retention is assured by the attachment, and the high precision millings, meaning the shoulders and interlocks, guides support and stabilized the prosthesis. The composite solutions implies specific acknowledgments and performing laboratory endowment (1-6). Their technology brings often the need for joining dissimilar alloys.

Objectives

The aim of the study was to provide information for successfully joining of used alloy combinations.

Material and Methods

Microplasma welding allow to combine telescopic crowns with other types of attachments through secondary crown welding with metallic saddle of removable partial dentures, separately cast (Fig. 1-4). This manouvre is necessary for achieving of a high precision joining which doesn't deform the shape and position of telescopic crown.

Fig. 1: Telescopic crown framework with medial extension for welding

Fig. 2: Removable partial denture framework after deflasking

Fig. 3: Welded framework applies on the cast

Fig. 4: Welding detail of telescopic crown to removable partial denture framework

The main advantages of microplasma welding are represented by the fact that the welding can be done directly on the working cast and one can work near the resins or ceramics without affecting them. This fact determines time saving. The reduced thermal influence implies minimal deformation of the metallic framework.

The welding presents some particularities depending on alloys composition and structures which must be welded. Because of, in the case of composite denture manufactory, it is necessary to combine two different alloys, one used for fixed compounds and other for removable compound, experimental analyses of dissimilar bonds were made.

Cast plates from Ni-Cr (Wiron 99, Wirocer plus, Bego, Bremen, Germany) and Co-Cr (Wironit extrahard, Bego, Bremen, Germany) dental base alloys were cast. They were welded using microplasma welding device (Schütz Dental, Rosbach, Germany) in butt joint configuration, with and without filling material. The following process parameters were varied: power, time delay, meanwhile the argon quantity was maintained constantly. For plates welding following parameters were used: power 5, time delay 40 ms, argon quantity 5 liters/min. For filling material deposition the parameters were: power 4, time delay 35 ms, and the same argon quantity. For modeling and smoothing: power 2, time delay 45 ms.

Welded specimens were analyzed macroscopically, microstructural and the microhardness were determined in the base metal (BM), welded metal (WM) and heat affected zone (HAZ).

Results

Metallographic analyses (Fig. 5, 6) and microhardness tests showed structural changes particularly in the HAZ, with precipitates of some compounds, which harden the respective area. The microhardness increasing in HAZ is not significant (table I). The cracks appear in welded material (WM) mostly at joints without filling material. Microcracks appeared also in Ni-Cr alloy. Wasn't observed significant differences at welding with different materials.

Conclusions

Microplasma welding is applicable in joining of alloys with different composition. It makes possible obtaining of some high precision prosthetic pieces, which can satisfy actual exactness. The microstructure depends on the processing parameters and the composition of the filler material.
